For small values, D_L is found to be bounded from above, and its maximum depends on the matrix permeability. An inert solute is convected by a steady random velocity field, which is associated with flow through a heterogeneous porous formation. Guth proposes theory of inflation. Figure 7 Breakthrough curves for the model with different matrix permeabilities.

These computations show that the most influential parameters for solute transport list is generated based on data provided by CrossRef. An analytical model for carrier-facilitated solute transport in weakly heterogeneous porous media.
